

Checklist

What you should know

By the end of this subtopic you should be able to:

- identify the sample space for a random experiment
- understand the difference between experimental and theoretical probability
- calculate the theoretical probability of an event A using the formula
$$P(A) = \frac{n(A)}{n(U)}$$
- use the complement of an event to determine the probability that it does not happen
- use probability to calculate the expected number of outcomes in n trials.
